

Трансформации автомобилей

Инструменты:

1. [ChatGPT](#)
2. [Flow AI](#)

PROMPT 1 (Используется для запроса на создание изображения):

You are an automotive historian and expert AI image-prompt writer.

Your task is to research real production cars and generate highly detailed, professional-grade image prompts for a car evolution video, where the user uploads an image and each new prompt replaces the car with the next model, while everything else in the image remains unchanged.

The prompts must produce sharp, realistic results, comparable to high-end automotive photography.

STEP 1 — ASK THE USER (MANDATORY)

Before generating anything, ask ALL of the following questions and wait for answers:

1. Which car company or specific car model do you want the evolution video for?
2. Which evolution type do you want?
 - A) First production model → latest current model
 - B) One specific model across all generations
 - C) Custom year range

3. If you chose option C, specify the start year and end year.
(If not, say “skip”.)

Do NOT proceed until all answers are provided.

STEP 2 — RESEARCH (SILENT, COMPLETE)

After the user answers:

- Research real automotive history
- Identify ALL major production models or generations
- Do NOT limit the number of models
- Do NOT skip important generations
- Exclude concept cars unless explicitly requested

Accuracy is mandatory.

STEP 3 — OUTPUT FORMAT (STRICT)

Your output must contain ONLY TWO SECTIONS, formatted exactly as follows.

♦ SECTION 1: COMPLETE EVOLUTION LIST

(Text only, no explanations)

Example format:

BMW M5 E28 – 1985
BMW M5 E34 – 1988
BMW M5 E39 – 1998
BMW M5 E60 – 2005
BMW M5 F10 – 2011
BMW M5 F90 – 2018

♦ SECTION 2: IMAGE PROMPTS

(HEADINGS + DETAILED PROMPTS)

RULES FOR THIS SECTION

- Each model MUST have:
 - A clear heading with model name
 - The prompt written below it
- Prompts must:
 - Assume the user uploads the previous image
 - Say “replace the car in the uploaded image”
 - Describe ONLY the car
 - Be technically detailed
- Do NOT describe the background
- Do NOT mention camera specs
- Do NOT mention “reference image”

♦ FIRST MODEL (NO IMAGE REPLACEMENT)

[MODEL NAME + YEAR]

Photorealistic image of [MODEL NAME + YEAR].

[Highly detailed description of the car: body style, construction, materials, wheels, lighting hardware, proportions, era-specific design language].

Historically accurate design.

Natural lighting.

Sharp details and realistic reflections.

Looks like a real professional automotive photograph.

♦ ALL NEXT MODELS (IMAGE REPLACEMENT)

For every next model, use this structure:

[NEXT MODEL NAME + YEAR]

Replace the car in the uploaded image with [MODEL NAME + YEAR].

Update the vehicle to accurately match its real-world design, including [clear, detailed description of how this model differs: body shape, size, construction method, wheels, lighting design, stance, proportions, era changes].

Correct scale and realistic construction.

Everything else in the image remains unchanged.

Photorealistic, sharp details, natural photographic look.

Repeat this heading + prompt format for EVERY model in the evolution list, without skipping any.

IMPORTANT RULES (DO NOT BREAK)

- Do NOT compress or shorten prompts
- Do NOT limit the number of models
- Do NOT add background descriptions
- Do NOT use generic one-line prompts
- Detail must come from car design, not buzzwords

FINAL RULE

You are NOT generating images.

You are generating research-accurate, highly detailed, heading-based image prompts optimized for a manual image-upload and car-replacement workflow.

PROMPT 2 (Используется для генерации фона):

Ultra-realistic wide-angle photograph of an empty countryside highway, captured from a very low camera height close to the asphalt, with the camera placed on the left side of the road and pointed forward-right, so the road enters from the bottom left foreground and recedes diagonally toward the far right horizon,

creating a strong asymmetric perspective. The highway is multi-lane with white dashed lane markings, realistic asphalt texture, and metal guardrails running along both sides. Trees and bushes line the roadside and appear horizontally motion-blurred, as if the image was taken from a fast-moving vehicle, while the road surface remains sharp. The composition is intentionally off-center, not symmetrical, not straight-ahead, with the vanishing point pushed to the right edge of the frame. Natural daylight, clear pale blue sky, neutral color grading, realistic exposure, no dramatic lighting, true-to-life tones, DSLR realism, 24mm wide-angle lens, tracking shot feel, high-resolution, extremely realistic, stock photography style.

PROMPT 3 (Используется для создания видео):

Create a photorealistic frames-to-video transformation where the car in Frame 1 mechanically evolves into the car in Frame 2 while the background remains completely unchanged, set on a clean open highway road with smooth asphalt texture, subtle lane markings, distant greenery on both sides, and a clear daylight sky, using a fixed low front three-quarter camera angle with no camera movement, no zoom, and no framing change; the transformation must be physical and mechanical like a Transformers-style engineering evolution where the chassis lengthens and restructures, suspension height adjusts realistically, axles reposition, wheels increase in diameter and width, tires reform with correct proportions, body panels detach, slide, rotate, expand, and reassemble, the hood elongates, fenders reshape, doors reform, the roofline and cabin volume evolve step by step, the grille and headlights mechanically redesign piece by piece, materials transition realistically from older metal construction to modern finishes, all motion is smooth and continuous with visible intermediate stages, no fades, no dissolves, no melting or liquid morphing, no glowing effects or particles, realistic reflections and shadows are preserved, the car remains grounded to the road at all times, lighting stays consistent with the environment, the video starts exactly matching Frame 1 and ends exactly matching Frame 2, and the final result looks like a high-end automotive VFX shot showing a precise, engineered evolution from the first car to the second.

Если видео промпт дает жесткие фриззы, тогда используй этот промпт

Create a photorealistic video shot where the car from Frame 1 transforms into a different car model inspired by Frame 2 through a complex, rigid mechanical Transformers-style process. The background is a clean open highway with smooth asphalt, subtle lane markings, distant greenery on both sides, and a clear daytime sky. Use a fixed low front three-quarter camera angle on a tripod: no camera

movement, no zoom, no reframing. The car stays firmly grounded on the road and may roll slowly forward with realistic wheel rotation and subtle suspension movement.

Reveal the internal mechanical skeleton of the car: structural frame, ribs, hinges, pistons, gears, shafts, linkages, and brackets. The transformation is driven by solid mechanical parts, not soft morphing. Body panels slide along visible rails, rotate around hinges, fold, extend, and lock into new positions. Windows roll down and up, glass panels retract and extend, doors shift and reattach in new positions, the roofline changes segment by segment. The chassis stretches in discrete sections, suspension compresses or extends realistically, axles physically shift, wheels detach and reattach in larger sizes, and tires expand and widen as solid rubber shapes.

Show many small parts moving at once: gears spinning, inner beams rotating, mechanical arms pushing and pulling panels into place, exposing the inner skeleton before it is covered again. Every visible change must come from rigid parts moving, sliding, rotating, folding, and snapping into place like real robotics and automotive engineering, not from shapes blending or warping.

Avoid soft morphing and warping: no liquid or rubbery transitions, no cross-dissolves or fades between forms, no magical glowing energy or particles. Each frame should show clear, readable mechanical motion of solid parts, with temporary gaps, overlaps, and joints as the car reconfigures. Preserve realistic reflections and shadows and keep lighting fully consistent with the static environment for the whole shot.

The transformation progresses continuously from the first frame toward the design language of the car in Frame 2. Physically believable mechanical motion is more important than a perfect pixel match to the reference. If the model cannot reach an exact copy of Frame 2 without a sudden snap, it must keep the transformation mechanically continuous and avoid any abrupt redraw or jump into the final reference image. The video should feel like one continuous, physically plausible engineering evolution from the first car into a more modern car inspired by the second frame, with no pause, no static hold, and no sudden pop at the end
